ABSTRACT. Probabilistic automata (PA), also known as probabilistic nondeterministic labelled transition systems, combine probability and nondeterminism. They can be given different semantics, like strong bisimilarity, convex bisimilarity, or (more recently) distribution bisimilarity. The latter is based on the view of PA as transformers of probability distributions, also called belief states, and promotes distributions to first-class citizens.

We give a coalgebraic account of the latter semantics, and explain the genesis of the belief-state transformer from a PA. To do so, we make explicit the convex algebraic structure present in PA and identify belief-state transformers as transition systems with state space that carries a convex algebra. As a consequence of our abstract approach, we can give a sound proof technique which we call bisimulation up-to convex hull.

1. INTRODUCTION

Probabilistic automata (PA), closely related to Markov decision processes (MDPs), have been used along the years in various areas of verification [LMOW08, KNP11, KNSS02, BK08], machine learning [GMR+12, MCJ+16], and semantics [WJV+15, SK12]. Recent interest in research around semantics of probabilistic programming languages has led to new insights in connections between category theory, probability theory, and automata [SYW+16, DDG16, HKSY17, Sta17, Mis17].

PA have been given various semantics, starting from strong bisimilarity [LS91], probabilistic (convex) bisimilarity [SL94, Seg95], to bisimilarity on distributions [DHR08, DvGHM08, CPP09, EHZ10, CR11, Hen12, FZ14, HKK14]. In this last view, probabilistic automata are understood as transformers of belief states, labeled transition systems (LTSs) having as states probability distributions, see e.g. [DvGHM08, DvGHM09, KVAK10, AAGT12, DH13, FZ14, DMS14]. Checking such equivalence raises a lot of challenges since belief-states are

uncountable. Nevertheless, it is decidable [HKK14, EHK$^+$13] with help of convexity. Despite these developments, what remains open is the understanding of the genesis of belief-state transformers and canonicity of distribution bisimilarity, as well as the role of convex algebras.

The theory of coalgebras [Jac16, Rut00, JR97] provides a toolbox for modelling and analysing different types of state machines. In a nutshell, a coalgebra is an arrow $c\colon S \to FS$ for some functor $F\colon \mathbf{C} \to \mathbf{C}$ on a category $\mathbf{C}$. Intuitively, S represents the space of states of the machine, c its transition structure and the functor F its type. Most importantly, every functor gives rise to a canonical notion of behavioural equivalence ($\approx$), a coinductive proof technique and, for finite states machines, a procedure to check $\approx$.

By tuning the parameters $\mathbf{C}$ and F, one can retrieve many existing types of machines and their associated equivalences. For instance, by taking $\mathbf{C} = \mathbf{Sets}$, the category of sets and functions, and $FS = (\mathcal{P}\mathcal{D}S)^L$, the set of functions from L to subsets ($\mathcal{P}$) of probability distributions ($\mathcal{D}$) over S, coalgebras $c\colon S \to FS$ are in one-to-one correspondence with PA with labels in L. Moreover, the associated notion of behavioural equivalence turns out to be the classical strong probabilistic bisimilarity of [LS91] (see [BSdV04, Sok11] for more details). Recent work [Mio14] shows that, by taking a slightly different functor, forcing the subsets to be convex, one obtains probabilistic (convex) bisimilarity as in [SL94, Seg95].

In this paper, we take a coalgebraic outlook at the semantics of probabilistic automata as belief-state transformers: we wish to translate a PA $c\colon S \to (\mathcal{P}\mathcal{D}S)^L$ into a belief state transformer $c^{\sharp}\colon \mathcal{D}S \to (\mathcal{P}\mathcal{D}S)^L$. Note that the latter is a coalgebra for the functor $FX = (\mathcal{P}X)^L$, i.e., a labeled transition system, since the state space is the set of probability distributions $\mathcal{D}S$. This is reminiscent of the standard determinisation for non-deterministic automata (NDA) seen as coalgebras $c\colon S \to 2 \times (\mathcal{P}S)^L$. The result of the determinisation is a deterministic automaton $c^{\sharp}\colon \mathcal{P}S \to 2 \times (\mathcal{P}S)^L$ (with state space $\mathcal{P}S$), which is a coalgebra for the functor $FX = 2 \times X^L$. In the case of PA, one lifts the states space to $\mathcal{D}S$, in the one of NDA to $\mathcal{P}S$. From an abstract perspective, both $\mathcal{D}$ and $\mathcal{P}$ are monads, hereafter denoted by $\mathcal{M}$, and both PA and NDA can be regarded as coalgebras of type $c\colon S \to F\mathcal{M}S$.

In [SBBR10], a generalised determinisation transforming coalgebras $c\colon S \to F\mathcal{M}S$ into coalgebras $c^{\sharp}\colon \mathcal{M}S \to F\mathcal{M}S$ was presented. This construction requires the existence of a *lifting* $\overline{F}$ of F to the category of algebras for the monad $\mathcal{M}$. In the case of NDA, the functor $FX = 2 \times X^L$ can be easily lifted to the category of join-semilattices (algebras for $\mathcal{P}$) and, the coalgebra $c^{\sharp}\colon \mathcal{P}S \to 2 \times (\mathcal{P}S)^L$ resulting from this construction turns out to be exactly the standard determinised automaton. Unfortunately, this is not the case with probabilistic automata: because of the lack of a suitable distributive law of $\mathcal{D}$ over $\mathcal{P}$ [VW06], it is impossible to suitably lift $FX = (\mathcal{P}X)^L$ to the category of *convex algebras* (algebras for the monad $\mathcal{D}$).

The way out of the impasse consists in defining a powerset-like functor on the category of convex algebras. This is not a lifting but it enjoys enough properties that allow to lift every PA into a labeled transition system on convex algebras. In turn, these can be transformed – without changing the underlying behavioural equivalence – into standard LTSs on **Sets** by simply forgetting the algebraic structure. We show that the result of the whole procedure is exactly the expected belief-state transformer and that the induced notion of behavioural equivalence coincides with a canonical one present in the literature [DvGHM08, Hen12, FZ14, HKK14].

The analogy with NDA pays back in terms of proof techniques. In [BP13], Bonchi and Pous introduced an efficient algorithm to check language equivalence of NDA based
Figure 1: On the left: a PA with set of actions $L = \{a\}$ and set of states $S = \{x_0, x_1, x_2, x_3, y_0, y_1, y_2, y_3\}$. We depict each transition $s \xrightarrow{a} \zeta$ in two stages: a straight action-labeled arrow from s to $\cdot$ and then several dotted arrows from $\cdot$ to states in S specifying the distribution ζ. On the right: part of the corresponding belief-state transformer. The dots between two arrows $\zeta \xrightarrow{a} \xi_1$ and $\zeta \xrightarrow{a} \xi_2$ denote that ζ can perform infinitely many transitions to states obtained as convex combinations of ξ_1 and ξ_2. For instance $y_0 \xrightarrow{a} \frac{1}{4}y_1 + \frac{1}{4}y_2 + \frac{1}{2}y_3$.

on coinduction up-to [PS11]: in a determinised automaton $c^\sharp \colon \mathcal{P}S \to 2 \times (\mathcal{P}S)^L$, language equivalence can be proved by means of bisimulations up-to the structure of join semilattice carried by the state space $\mathcal{P}S$. Algorithmically, this results in an impressive pruning of the search space.

Similarly, in a belief-state transformer $c^\sharp \colon \mathcal{D}S \to (\mathcal{P}\mathcal{D}S)^L$, one can coinductively reason up-to the convex algebraic structure carried by $\mathcal{D}S$. The resulting proof technique, which we call in this paper *bisimulation up-to convex hull*, allows finite relations to witness the equivalence of infinitely many states. More precisely, by exploiting a recent result in convex algebra by Sokolova and Woracek [SW15], we are able to show that the equivalence of any two belief states can always be proven by means of a *finite* bisimulation up-to.

The paper starts with background on PA (Section 2), convex algebras (Section 3), and coalgebra (Section 4). We provide the PA functor on convex algebras in Section 5. We give the transformation from PA to belief-state transformers in Section 6 and prove the coincidence of the abstract and concrete transformers and semantics. We present bisimulation up-to convex hull and prove soundness in Section 7.

2. Probabilistic Automata

Probabilistic automata are models of systems that involve both probability and nondeterminism. We start with their definition by Segala and Lynch [SL94].

Definition 2.1. A probabilistic automaton (PA) is a triple $M = (S, L, \to)$ where S is a set of states, L is a set of actions or action labels, and $\to \subseteq S \times L \times \mathcal{D}(S)$ is the transition relation. As usual, $s \xrightarrow{a} \zeta$ stands for $(s, a, \zeta) \in \to$. $\diamond$

An example is shown on the left of Figure 1. Probabilistic automata can be given different semantics, e.g., (strong probabilistic) bisimilarity [LS91], convex (probabilistic) bisimilarity [SL94], and as transformers of belief states [CPP09, FZ14, DH13, DvGHM09,

DvGHM08, HKK14] whose definitions we present next. For the rest of the section, we fix a PA $M = (S, L, \rightarrow)$.

Definition 2.2 (Strong Probabilistic Bisimilarity). A relation $R \subseteq S \times S$ is a (strong probabilistic) *bisimulation* if $(s, t) \in R$ implies, for all actions $a \in L$ and all $\xi \in \mathcal{D}(S)$, that

$$s \xrightarrow{a} \xi \Rightarrow \exists \xi' \in \mathcal{D}(S). \ t \xrightarrow{a} \xi' \wedge \xi \equiv_R \xi', \quad \text{and} \quad t \xrightarrow{a} \xi' \Rightarrow \exists \xi \in \mathcal{D}(S). \ s \xrightarrow{a} \xi \wedge \xi \equiv_R \xi'.$$

Here, $\equiv_R \subseteq \ \mathcal{D}(S) \times \mathcal{D}(S)$ is the lifting of R to distributions, defined by $\xi \equiv_R \xi'$ if and only if there exists a distribution $\nu \in \mathcal{D}(S \times S)$ such that

1. $\sum_{t \in S} \nu(s, t) = \xi(s)$ for any $s \in S$,
2. $\sum_{s \in S} \nu(s, t) = \xi'(t)$ for any $t \in T$, and
3. $\nu(s, t) \neq 0$ implies $(s, t) \in R$.

Two states s and t are (strongly probabilistically) *bisimilar*, notation $s \sim t$, if there exists a (strong probabilistic) bisimulation R with $(s, t) \in R$. ◇

Definition 2.3 (Convex Bisimilarity). A relation $R \subseteq S \times S$ is a *convex* (probabilistic) *bisimulation* if $(s, t) \in R$ implies, for all actions $a \in L$ and all $\xi \in \mathcal{D}(S)$, that

$$s \xrightarrow{a} \xi \Rightarrow \exists \xi' \in \mathcal{D}(S). \ t \xrightarrow{a}_c \xi' \wedge \xi \equiv_R \xi', \quad \text{and} \quad t \xrightarrow{a} \xi' \Rightarrow \exists \xi \in \mathcal{D}(S). \ s \xrightarrow{a}_c \xi \wedge \xi \equiv_R \xi'.$$

Here $\rightarrow_c$ denotes the convex transition relation, defined as follows: $s \xrightarrow{a}_c \xi$ if and only if $\xi = \sum_{i=1}^{n} p_i \xi_i$ for some $\xi_i \in \mathcal{D}(S)$ and $p_i \in [0, 1]$ satisfying $\sum_{i=1}^{n} p_i = 1$ and $s \xrightarrow{a} \xi_i$ for $i = 1, \ldots, n$. Two states s and t are *convex bisimilar*, notation $s \sim_c t$, if there exists a convex bisimulation R with $(s, t) \in R$. ◇

Convex bisimilarity is (strong probabilistic) bisimilarity on the "convex closure" of the given PA. More precisely, consider the PA $M_c = (S, L, \rightarrow_c)$ in which $s \xrightarrow{a}_c \xi$ whenever $s \in S$ and ξ is in the convex hull (see Section 3 for a definition) of the set $\{\zeta \in \mathcal{D}(S) \mid s \xrightarrow{a} \zeta\}$. Then convex bisimilarity of M is bisimilarity of M_c. Hence, if bisimilarity is the behavioural equivalence of interest, we see that convex semantics arises from a different perspective on the representation of a PA: instead of seeing the given transitions as independent, we look at them as generators of infinitely many transitions in the convex closure.

There is yet another way to understand PA, as belief-state transformers, present but sometimes implicit in [CPP09, Hen12, FZ14, DH13, DvGHM09, DvGHM08, HKK14, CR11] to name a few, with behavioural equivalences on distributions. We were particularly inspired by the original work of Deng et al. [DH13, DvGHM09, DvGHM08] as well as [HKK14]. Given a PA $M = (S, L, \rightarrow)$, consider the labeled transition system $M_{bs} = (\mathcal{D}S, L, \mapsto)$ with states distributions over the original states of M, and transitions $\mapsto \subseteq \ \mathcal{D}S \times L \times \mathcal{D}S$ defined by

$$\xi \xmapsto{a} \zeta \quad \text{iff} \quad \xi = \sum p_i s_i, \ s_i \xrightarrow{a}_c \xi_i, \ \zeta = \sum p_i \xi_i.$$

We call M_{bs} the belief-state transformer of M. Figure 1, right, displays a part of the belief-state transformer induced by the PA of Figure 1, left. According to this definition, a distribution makes an action step only if all its support states can make the step.

This, and hence the corresponding notion of bisimulation, can vary. For example, in [HKK14] a distribution makes a transition $\xmapsto{a}$ if some of its support states can perform an $\xmapsto{a}$ step. There are several proposed notions of equivalences on distributions [Hen12, DHR08, DMS14, FZ14, DH13, CPP09, HKK14] that mainly differ in the treatment of termination. See [HKK14] for a detailed comparison.

In this paper we focus on *full* probability distributions for reasons of clarity and canonical presentation. This has some effect on the obtained semantics (and can lead to undesired corner cases). However, all our results can be recast in the setting of subprobability distributions too, yielding a more natural semantics on the expense of more complicated presentation.

Definition 2.4 (Distribution Bisimilarity)**.** An equivalence $R \subseteq \mathcal{D}S \times \mathcal{D}S$ is a distribution bisimulation of M if and only if it is a bisimulation of the belief-state transformer M_{bs}.

Two distributions ξ and ζ are *distribution bisimilar*, notation $\xi \sim_d \zeta$, if there exists a bisimulation R with $(\xi, \zeta) \in R$. Two states s and t are *distribution bisimilar*, notation $s \sim_d t$, if $\delta_s \sim_d \delta_t$, where δ_x denotes the Dirac distribution with $\delta_x(x) = 1$. $\diamond$

While the foundations of strong probabilistic bisimilarity are well-studied [Sok11, BSdV04, VR99] and convex probabilistic bisimilarity was also recently captured coalgebraically [Mio14], the foundations of the semantics of PA as transformers of belief states is not yet explained. One of the goals of the present paper is to show that also that semantics (naturally on distributions [HKK14]) is an instance of generic behavioural equivalence. Note that a (somewhat concrete) proof is given for the bisimilarity of [HKK14] — the authors have proven that their bisimilarity is coalgebraic bisimilarity of a certain coalgebra corresponding to the belief-state transformer. What is missing there, and in all related work, is an explanation of the relationship of the belief-state transformer to the the original PA. Clarifying the foundations of the belief-state transformer and the distribution bisimilarity is our initial motivation.

3. Convex Algebras

By $\mathcal{C}$ we denote the signature of convex algebras

$$\mathcal{C} = \{(p_i)_{i=0}^n \mid n \in \mathbb{N}, p_i \in [0,1], \sum_{i=0}^n p_i = 1\}.$$

The operation symbol $(p_i)_{i=0}^n$ has arity $(n+1)$ and it will be interpreted by a convex combination with coefficients p_i for $i = 0, \ldots, n$. For $p \in [0,1]$ we write $\bar{p} = 1 - p$.

Definition 3.1. A *convex algebra* $\mathbb{X}$ is an algebra with signature $\mathcal{C}$, i.e., a set X together with an operation $\sum_{i=0}^n p_i(-)_i$ for each operational symbol $(p_i)_{i=0}^n \in \mathcal{C}$, such that the following two axioms hold:

- Projection: $\sum_{i=0}^n p_i x_i = x_j$ if $p_j = 1$.
- Barycenter: $\sum_{i=0}^n p_i \left(\sum_{j=0}^m q_{i,j} x_j \right) = \sum_{j=0}^m \left(\sum_{i=0}^n p_i q_{i,j} \right) x_j$.

A convex algebra homomorphism h from $\mathbb{X}$ to $\mathbb{Y}$ is a *convex* (synonymously, *affine*) map, i.e., $h \colon X \to Y$ with the property $h\left(\sum_{i=0}^n p_i x_i \right) = \sum_{i=0}^n p_i h(x_i)$. $\diamond$

Remark 3.2. Let $\mathbb{X}$ be a convex algebra. Then (for $p_n \neq 1$)

$$\sum_{i=0}^n p_i x_i = \overline{p_n} \left(\sum_{j=0}^{n-1} \frac{p_j}{\overline{p_n}} x_j \right) + p_n x_n \tag{3.1}$$

Hence, an $(n+1)$-ary convex combination can be written as a binary convex combination using an n-ary convex combination. As a consequence, if X is a set that carries two convex

algebras $\mathbb{X}_1$ and $\mathbb{X}_2$ with operations $\sum_{i=0}^{n} p_i(-)_i$ and $\bigoplus_{i=0}^{n} p_i(-)_i$, respectively (and binary versions $+$ and $\oplus$, respectively) such that $px + \bar{p}y = px \oplus \bar{p}y$ for all p, x, y, then $\mathbb{X}_1 = \mathbb{X}_2$.

One can also see (3.1) as a definition, see e.g. [Sto49, Definition 1]. We make the connection explicit with the next proposition, cf. [Sto49, Lemma 1-Lemma 4][1].

Proposition 3.3. *Let X be a set with binary operations $px + \bar{p}y$ for $x, y \in X$ and $p \in (0, 1)$. For $x, y, z \in X$ and $p, q \in (0, 1)$, assume*
- *Idempotence: $px + \bar{p}x = x$,*
- *Parametric commutativity: $px + \bar{p}y = \bar{p}y + px$,*
- *Parametric associativity: $p(qx + \bar{q}y) + \bar{p}z = pqx + \overline{pq}\left(\frac{p\bar{q}}{\overline{pq}}y + \frac{\bar{p}}{\overline{pq}}z\right)$,*

and define n-ary convex operations by the projection axiom and the formula (3.1). Then X becomes a convex algebra. $\qquad\square$

Hence, it suffices to consider binary convex combinations only, whenever more convenient.

Definition 3.4. Let $\mathbb{X}$ be a convex algebra, with carrier X and $C \subseteq X$. C is *convex* if it is the carrier of a subalgebra of $\mathbb{X}$, i.e., if $px + \bar{p}y \in C$ for $x, y \in C$ and $p \in (0, 1)$. The *convex hull* of a set $S \subseteq X$, denoted $\mathrm{conv}(S)$, is the smallest convex set that contains S. $\qquad\diamond$

Clearly, a set $C \subseteq X$ for X being the carrier of a convex algebra $\mathbb{X}$ is convex if and only if $C = \mathrm{conv}(C)$. Convexity plays an important role in the semantics of probabilistic automata, for example in the definition of convex bisimulation, Definition 2.3.

4. Coalgebras and Generalised Determinisation

In this section we give a gentle introduction to (co)algebra that enables us to highlight the generic principles behind the semantics of probabilistic automata. The interested reader is referred to [Jac16, Rut00, JR97] for more details. We start by recalling even the basic notions of category, functor and natural transformation, so that all of the results in the paper are accessible also to non-experts.

A category $\mathbf{C}$ is a collection of objects and a collection of arrows (or morphisms) from one object to another. For every object $X \in \mathbf{C}$, there is an identity arrow $id_X \colon X \to X$. For any three objects $X, Y, Z \in \mathbf{C}$, given two arrows $f \colon X \to Y$ and $g \colon Y \to Z$, there exists an arrow $g \circ f \colon X \to Z$. Arrow composition is associative and id_X is neutral w.r.t. composition. The standard example is **Sets**, the category of sets and functions.

A functor F from a category $\mathbf{C}$ to a category $\mathbf{D}$, notation $F \colon \mathbf{C} \to \mathbf{D}$, assigns to every object $X \in \mathbf{C}$, an object $FX \in \mathbf{D}$, and to every arrow $f \colon X \to Y$ in $\mathbf{C}$ an arrow $Ff \colon FX \to FY$ in $\mathbf{D}$ such that identity arrows and composition are preserved.

Example 4.1. Examples of functors on **Sets** which are of interest to us are:
(1) The constant exponent functor $(-)^L$ for a set L, mapping a set X to the set X^L of all functions from L to X, and a function $f \colon X \to Y$ to $f^L \colon X^L \to Y^L$ with $f^L(g) = f \circ g$.
(2) The powerset functor $\mathcal{P}$ mapping a set X to its powerset $\mathcal{P}X = \{S \mid S \subseteq X\}$ and on functions $f \colon X \to Y$ given by direct image: $\mathcal{P}f \colon \mathcal{P}X \to \mathcal{P}Y$, $\mathcal{P}(f)(S) = \{f(s) \mid s \in S\}$.

---

[1]Stone's cancellation Postulate V is not used in his Lemma 1-Lemma 4.

(3) The finitely supported probability distribution functor $\mathcal{D}$ is defined, for a set X and a function $f\colon X \to Y$, as

$$\mathcal{D}X \quad = \quad \{\varphi\colon X \to [0,1] \mid \sum_{x \in X} \varphi(x) = 1, \operatorname{supp}(\varphi) \text{ is finite}\}$$

$$\mathcal{D}f(\varphi)(y) \quad = \quad \sum_{x \in f^{-1}(y)} \varphi(x).$$

The support set of a distribution $\varphi \in \mathcal{D}X$ is defined as

$$\operatorname{supp}(\varphi) = \{x \in X \mid \varphi(x) \neq 0\}.$$

(4) The functor C [Mio14, Jac08, Var03] maps a set X to the set of all nonempty convex subsets of distributions over X, and a function $f\colon X \to Y$ to the function $\mathcal{P}\mathcal{D}f$.

We will often decompose $\mathcal{P}$ as $\mathcal{P}_{ne} + 1$ where $\mathcal{P}_{ne}$ is the nonempty powerset functor and $(-) + 1$ is the termination functor defined for every set X by $X + 1 = X \cup \{*\}$ with $* \notin X$ and every function $f\colon X \to Y$ by $f + 1(*) = *$ and $f + 1(x) = f(x)$ for $x \in X$.

A category $\mathbf{C}$ is concrete, if it admits a canonical forgetful functor $\mathcal{U}\colon \mathbf{C} \to \mathbf{Sets}$. By a forgetful functor we mean a functor that is identity on arrows. Intuitively, a concrete category has objects that are sets with some additional structure, e.g. algebras, and morphisms that are particular kind of functions.

Let $F\colon \mathbf{C} \to \mathbf{D}$ and $G\colon \mathbf{C} \to \mathbf{D}$ be two functors. A natural transformation $\sigma\colon F \Rightarrow G$ is a family of arrows $\sigma_X\colon FX \to GX$ in $\mathbf{D}$ such that the diagram on the right commutes for all arrows $f\colon X \to Y$.

$$\begin{array}{ccc} FX & \xrightarrow{Ff} & FY \\ \sigma_X \downarrow & & \downarrow \sigma_Y \\ GX & \xrightarrow{Gf} & GY \end{array}$$

Coalgebras provide an abstract framework for state-based system. Let $\mathbf{C}$ be a base category. A coalgebra is a pair (S, c) of a state space S (object in $\mathbf{C}$) and an arrow $c\colon S \to FS$ in $\mathbf{C}$ where $F\colon \mathbf{C} \to \mathbf{C}$ is a functor that specifies the type of transitions. We will sometimes just say the coalgebra $c\colon S \to FS$, meaning the coalgebra (S, c). A coalgebra homomorphism from a coalgebra (S, c) to a coalgebra (T, d) is an arrow $h\colon S \to T$ in $\mathbf{C}$ that makes the diagram below on the right commute. Coalgebras of a functor F and their coalgebra homomorphisms form a category that we denote by $\operatorname{Coalg}_{\mathbf{C}}(F)$.

Coalgebras over a concrete category, with $\mathcal{U}\colon \mathbf{C} \to \mathbf{Sets}$ being the forgetful functor, are equipped with a generic behavioural equivalence, which we define next. Let (S, c) be an F-coalgebra on a concrete category $\mathbf{C}$. An equivalence relation $R \subseteq \mathcal{U}S \times \mathcal{U}S$ is a kernel bisimulation (synonymously, a cocongruence) [Sta11, Kur00, Wol00] if it is the kernel of a homomorphism, i.e., $R = \ker \mathcal{U}h = \{(s, t) \in \mathcal{U}S \times \mathcal{U}S \mid \mathcal{U}h(s) = \mathcal{U}h(t)\}$ for some

$$\begin{array}{ccc} S & \xrightarrow{h} & T \\ c \downarrow & & \downarrow d \\ FS & \xrightarrow{Fh} & FT \end{array}$$

coalgebra homomorphism $h\colon (S, c) \to (T, d)$ to some F-coalgebra (T, d). Two states s, t of a coalgebra are behaviourally equivalent, notation $s \approx t$, iff there is a kernel bisimulation R with $(s, t) \in R$. It is not difficult to show that behaviour equivalence is itself a kernel bisimulation.

Moreover, coalgebras over a concrete category have a *set of states*, namely the set of states of (S, c) is $\mathcal{U}S$. The following property is simple but important: If there is a functor from one category of coalgebras (over a concrete category) to another that keeps the set of states the same and is identity on morphisms, then this functor preserves behavioural equivalence, i.e., if two states are equivalent in a coalgebra of the first category, then they are also equivalent in the image under the functor in the second category. More precisely,

let $\mathcal{T} \colon \mathrm{Coalg}_{\mathbf{C}}(F_{\mathbf{C}}) \to \mathrm{Coalg}_{\mathbf{D}}(F_{\mathbf{D}})$ for two concrete categories $\mathbf{C}$ and $\mathbf{D}$. Assume further that $U_{\mathbf{D}} \circ \mathcal{T} = U_{\mathbf{C}}$ for

$$U_{\mathbf{X}} \colon \mathrm{Coalg}_{\mathbf{X}}(F) \xrightarrow{\bar{U}_{\mathbf{X}}} \mathbf{X} \xrightarrow{\mathcal{U}_{\mathbf{X}}} \mathbf{Sets}$$

being the composition of the obvious forgetful functors with $\bar{U}_{\mathbf{X}}(S, c) = S$ and $\mathcal{U}_{\mathbf{X}}$ the forgetful functor making $\mathbf{X}$ concrete. Then $\mathcal{T}$ preserves behavioural equivalence. Note that $U_{\mathbf{D}} \circ \mathcal{T} = U_{\mathbf{C}}$ on objects means that $\mathcal{T}$ keeps the state set the same and $U_{\mathbf{D}} \circ \mathcal{T} = U_{\mathbf{C}}$ on morphisms means that $\mathcal{T}$ is identity on morphisms.

We are now in position to connect probabilistic automata to coalgebras.

Proposition 4.2 ([BSdV04, Sok11]). *A probabilistic automaton $M = (S, L, \to)$ can be identified with a $(\mathcal{P}\mathcal{D})^L$-coalgebra $c_M \colon S \to (\mathcal{P}\mathcal{D}S)^L$ on $\mathbf{Sets}$, where $s \xrightarrow{a} \xi$ in M iff $\xi \in c_M(s)(a)$ in (S, c_M). Bisimilarity in M equals behavioural equivalence in (S, c_M), i.e., for two states $s, t \in S$ we have $s \sim t \Leftrightarrow s \approx t$.* $\square$

It is also possible to provide convex bisimilarity semantics to probabilistic automata via coalgebraic behavioural equivalence, as the next proposition shows.

Proposition 4.3 ([Mio14]). *Let $M = (S, L, \to)$ be a probabilistic automaton, and let $(S, \bar{c}_M)$ be a $(C + 1)^L$-coalgebra on $\mathbf{Sets}$ defined by $\bar{c}_M(s)(a) = \mathrm{conv}(c_M(s)(a))$ if $c_M(s)(a) = \{\xi \mid s \xrightarrow{a} \xi\} \neq \emptyset$; and $\bar{c}_M(s)(a) = *$ if $c_M(s)(a) = \emptyset$. Convex bisimilarity in M equals behavioural equivalence in $(S, \bar{c}_M)$.* $\square$

The connection between (S, c_M) and $(S, \bar{c}_M)$ in Proposition 4.3 is the same as the connection between M and M_c in Section 2. Abstractly, it can be explained using the following well known generic property.

Lemma 4.4 ([Rut00, BSdV04]). *Let $\sigma \colon F \Rightarrow G$ be a natural transformation from $F \colon \mathbf{C} \to \mathbf{C}$ to $G \colon \mathbf{C} \to \mathbf{C}$. Then $\mathcal{T} \colon \mathrm{Coalg}_{\mathbf{C}}(F) \to \mathrm{Coalg}_{\mathbf{C}}(G)$ given by*

$$\mathcal{T}(S \xrightarrow{c} FS) = (S \xrightarrow{c} FS \xrightarrow{\sigma_S} GS)$$

on objects and identity on morphisms is a functor that preserves behavioural equivalence. If σ is injective, then $\mathcal{T}$ also reflects behavioural equivalence. $\square$

Example 4.5. We have that $\mathrm{conv} \colon \mathcal{P}\mathcal{D} \Rightarrow C + 1$ given by $\mathrm{conv}(\emptyset) = *$ and $\mathrm{conv}(X)$ is the already-introduced convex hull for $X \subseteq \mathcal{D}S$, $X \neq \emptyset$ is a natural transformation. Therefore, $\mathrm{conv}^L \colon (\mathcal{P}\mathcal{D})^L \Rightarrow (C + 1)^L$ is one as well, defined pointwise. As a consequence from Lemma 4.4, we get a functor $\mathcal{T}_{\mathrm{conv}} \colon \mathrm{Coalg}_{\mathbf{Sets}}((\mathcal{P}\mathcal{D})^L) \to \mathrm{Coalg}_{\mathbf{Sets}}((C + 1)^L)$ and hence bisimilarity implies convex bisimilarity in probabilistic automata.

On the other hand, we have the injective natural transformation $\iota \colon C + 1 \Rightarrow \mathcal{P}\mathcal{D}$ given by $\iota(X) = X$ and $\iota(*) = \emptyset$ yielding an injective natural transformation $\chi \colon (C + 1)^L \Rightarrow (\mathcal{P}\mathcal{D})^L$. As a consequence, convex bisimilarity coincides with strong bisimilarity on the "convex-closed" probabilistic automaton M_c, i.e., the coalgebra $(S, \bar{c}_M)$ whose transitions are all convex combinations of M-transitions.

4.1. **Algebras for a Monad.** The behaviour functor F often is, or involves, a monad $\mathcal{M}$, providing certain computational effects, such as partial, non-deterministic, or probabilistic computation.

More precisely, a monad is a functor $\mathcal{M}\colon \mathbf{C} \to \mathbf{C}$ together with two natural transformations: a unit $\eta\colon \mathrm{id}_{\mathbf{C}} \Rightarrow \mathcal{M}$ and multiplication $\mu\colon \mathcal{M}^2 \Rightarrow \mathcal{M}$. These are required to make the following diagrams commute, for $X \in \mathbf{C}$.

$$
\begin{array}{ccccc}
\mathcal{M}X & \xrightarrow{\ \eta_{\mathcal{M}X}\ } & \mathcal{M}^2X & \xleftarrow{\ \mathcal{M}\eta_X\ } & \mathcal{M}X \\
& \searrow & \downarrow{\scriptstyle\mu_X} & \swarrow & \\
& & \mathcal{M}X & &
\end{array}
\qquad\qquad
\begin{array}{ccc}
\mathcal{M}^3X & \xrightarrow{\ \mu_{\mathcal{M}X}\ } & \mathcal{M}^2X \\
{\scriptstyle \mathcal{M}\mu_X}\downarrow & & \downarrow{\scriptstyle \mu_X} \\
\mathcal{M}^2 & \xrightarrow{\ \mu_X\ } & \mathcal{M}X
\end{array}
$$

We briefly describe two examples of monads on **Sets**:

- The powerset monad $\mathcal{P}$, with unit given by singleton $\eta(x) = \{x\}$ and multiplication by union $\mu(\{X_i \in \mathcal{P}X \mid i \in I\}) = \bigcup_{i \in I} X_i$.
- The distribution monad $\mathcal{D}$, with unit given by a Dirac distribution $\eta(x) = \delta_x = (x \mapsto 1)$ for $x \in X$ and the multiplication by $\mu(\Phi)(x) = \sum\limits_{\varphi \in \mathrm{supp}(\Phi)} \Phi(\varphi) \cdot \varphi(x)$ for $\Phi \in \mathcal{D}\mathcal{D}X$.

With a monad $\mathcal{M}$ on a category $\mathbf{C}$ one associates the Eilenberg-Moore category $\mathrm{EM}(\mathcal{M})$ of Eilenberg-Moore algebras. Objects of $\mathrm{EM}(\mathcal{M})$ are pairs $\mathbb{A} = (A, a)$ of an object $A \in \mathbf{C}$ and an arrow $a\colon \mathcal{M}A \to A$, making the first two diagrams below commute.

$$
\begin{array}{ccc}
A & \xrightarrow{\ \eta\ } & \mathcal{M}A \\
& \searrow & \downarrow{\scriptstyle a} \\
& & A
\end{array}
\qquad
\begin{array}{ccc}
\mathcal{M}^2A & \xrightarrow{\ \mathcal{M}a\ } & \mathcal{M}A \\
{\scriptstyle \mu}\downarrow & & \downarrow{\scriptstyle a} \\
\mathcal{M}A & \xrightarrow{\ a\ } & A
\end{array}
\qquad
\begin{array}{ccc}
\mathcal{M}A & \xrightarrow{\ \mathcal{M}h\ } & \mathcal{M}B \\
{\scriptstyle a}\downarrow & & \downarrow{\scriptstyle b} \\
A & \xrightarrow{\ h\ } & B
\end{array}
$$

A homomorphism from an algebra $\mathbb{A} = (A, a)$ to an algebra $\mathbb{B} = (B, b)$ is a map $h\colon A \to B$ in $\mathbf{C}$ between the underlying objects making the diagram above on the right commute. The diagram in the middle thus says that the map a is a homomorphism from $(\mathcal{M}A, \mu_A)$ to $\mathbb{A}$. The forgetful functor $\mathcal{U}\colon \mathrm{EM}(\mathcal{M}) \to \mathbf{C}$ mapping an algebra to its carrier has a left adjoint $\mathcal{F}$, mapping an object $X \in \mathbf{C}$ to the (free) algebra $(\mathcal{M}X, \mu_X)$. We have that $\mathcal{M} = \mathcal{F} \circ \mathcal{U}$.

A category of Eilenberg-Moore algebras which is particularly relevant for our exposition is described in the following proposition. See [Ś74] and [Sem73] for the original result, but also [Dob06, Dob08] or [Jac10, Theorem 4] where a concrete and simple proof is given.

Proposition 4.6 ([Ś74, Dob06, Dob08, Jac10])**.** *Eilenberg-Moore algebras of the finitely supported distribution monad $\mathcal{D}$ are exactly convex algebras as defined in Section 3. The arrows in the Eilenberg-Moore category $\mathrm{EM}(\mathcal{D})$ are convex algebra homomorphisms.* $\qquad\square$

As a consequence, we will interchangeably use the abstract (Eilenberg-Moore algebra) and the concrete definition (convex algebra), whatever is more convenient. For the latter, we also just use binary convex operations, by Proposition 3.3, whenever more convenient.

4.2. **The Generalised Determinisation.** We now recall a construction from [SBBR10], which serves as source of inspiration for our work.

A functor $\overline{F}\colon \mathrm{EM}(\mathcal{M}) \to \mathrm{EM}(\mathcal{M})$ is said to be a lifting of a functor $F\colon \mathbf{C} \to \mathbf{C}$ if and only if $\mathcal{U} \circ \overline{F} = F \circ \mathcal{U}$. Here, $\mathcal{U}$ is the forgetful functor $\mathcal{U}\colon \mathrm{EM}(\mathcal{M}) \to \mathbf{C}$ mapping an algebra to its carrier. It has a left adjoint $\mathcal{F}$, mapping an object $X \in \mathbf{C}$ to the (free) algebra $(\mathcal{M}X, \mu_X)$. We have that $\mathcal{M} = \mathcal{U} \circ \mathcal{F}$.

Whenever $F\colon \mathbf{C} \to \mathbf{C}$ has a lifting $\overline{F}\colon \mathrm{EM}(\mathcal{M}) \to \mathrm{EM}(\mathcal{M})$, one has the following functors between categories of coalgebras.

$$\mathrm{Coalg}_{\mathbf{C}}\,(F\mathcal{M}) \xrightarrow{\ \overline{\mathcal{F}}\ } \mathrm{Coalg}_{\mathrm{EM}(\mathcal{M})}\,(\overline{F}) \xrightarrow{\ \overline{\mathcal{U}}\ } \mathrm{Coalg}_{\mathbf{C}}\,(F)$$

The functor $\overline{\mathcal{F}}$ transforms every coalgebra $c\colon S \to F\mathcal{M}S$ over the base category into a coalgebra $c^{\sharp}\colon \mathcal{F}S \to \overline{F}\mathcal{F}S$. Note that this is a coalgebra on $\mathrm{EM}(\mathcal{M})$: the state space carries an algebra, actually the freely generated one, and $c^{\sharp}$ is a homomorphism of $\mathcal{M}$-algebras. Intuitively, this amounts to compositionality: like in GSOS specifications, the transitions of a compound state are determined by the transitions of its components.

The functor $\overline{\mathcal{U}}$ simply forgets about the algebraic structure: $c^{\sharp}$ is mapped into

$$\mathcal{U}c^{\sharp}\colon \mathcal{M}S = \mathcal{U}\mathcal{F}S \to \mathcal{U}\overline{F}\mathcal{F}S = F\mathcal{U}\mathcal{F}S = F\mathcal{M}S.$$

An important property of $\overline{\mathcal{U}}$ is that it preserves and reflects behavioural equivalence. On the one hand, this fact usually allows to give concrete characterisation of $\approx$ for $\overline{F}$-coalgebras. On the other, it allows, by means of the so-called up-to techniques, to exploit the $\mathcal{M}$-algebraic structure of $\mathcal{F}S$ to check $\approx$ on $\mathcal{U}c^{\sharp}$.

By taking $F = 2 \times (-)^{L}$ and $\mathcal{M} = \mathcal{P}$, one transforms $c\colon S \to 2 \times (\mathcal{P}S)^{L}$ into $\mathcal{U}c^{\sharp}\colon \mathcal{P}S \to 2 \times (\mathcal{P}S)^{L}$. The former is a non-deterministic automaton (every c of this type is a pairing $\langle o, t \rangle$ of $o\colon S \to 2$, defining the final states, and $t\colon S \to \mathcal{P}(S)^{L}$, defining the transition relation) and the latter is a deterministic automaton which has $\mathcal{P}S$ as states space. In [SBBR10], see also [JSS15], it is shown that, for a certain choice of the lifting $\overline{F}$, this amounts exactly to the standard determinisation from automata theory. This explains why this construction is called *the generalised determinisation*.

In a sense, this is similar to the translation of probabilistic automata into belief-state transformers that we have seen in Section 2. Indeed, probabilistic automata are coalgebras $c\colon S \to (\mathcal{P}\mathcal{D}S)^{L}$ and belief state transformers are coalgebras of type $\mathcal{D}S \to (\mathcal{P}\mathcal{D}S)^{L}$. One would like to take $F = \mathcal{P}^{L}$ and $\mathcal{M} = \mathcal{D}$ and reuse the above construction but, unfortunately, $\mathcal{P}^{L}$ does *not* have a *suitable* lifting to $\mathrm{EM}(\mathcal{D})$. This is a consequence of two well known facts: the lack of a *suitable* distributive law $\rho\colon \mathcal{D}\mathcal{P} \Rightarrow \mathcal{P}\mathcal{D}$ [VW06] [2] and the one-to-one correspondence between distributive laws and liftings, see e.g. [JSS15]. In the next section, we will nevertheless provide a "powerset-like" functor on $\mathrm{EM}(\mathcal{D})$ that we will exploit then in Section 6 to properly model PA as belief-state transformers.

5. Coalgebras on Convex Algebras

In this section we provide several functors on $\mathrm{EM}(\mathcal{D})$ that will be used in the modelling of probabilistic automata as coalgebras over $\mathrm{EM}(\mathcal{D})$. This will make explicit the implicit algebraic structure (convexity) in probabilistic automata and lead to distribution bisimilarity as natural semantics for probabilistic automata in Section 6.

---

[2] As shown in [VW06], there is no distributive law of the powerset monad over the distribution monad. Note that a "trivial" lifting and a corresponding distributive law of the powerset *functor* over the distribution monad exists, it is based on [CR11] and has been exploited in [JSS15]. However, the corresponding "determinisation" is trivial, in the sense that its distribution bisimilarity coincides with bisimilarity, and it does not correspond to the belief-state transformer.

5.1. **Convex Powerset on Convex Algebras.** We now define a functor, the (nonempty) convex powerset functor, on $\mathrm{EM}(\mathcal{D})$. Let $\mathbb{A}$ be a convex algebra. We define $\mathcal{P}_c\mathbb{A}$ to be $\mathcal{P}_c\mathbb{A} = \mathbb{A}_c = (A_c, a_c)$ where

$$A_c = \{C \subseteq A \mid C \neq \emptyset, C \text{ is convex}\}$$

and a_c is the convex algebra structure given by the following *pointwise* binary convex combinations:

$$pC + \bar{p}D = \{pc + \bar{p}d \mid c \in C, d \in D\}.$$

It is important that we only allow nonempty convex subsets in the carrier A_c of $\mathcal{P}_c\mathbb{A}$, as otherwise the projection axiom fails.

For convex subsets of a finite dimensional vector space, the pointwise operations are known as the Minkowski addition and are a basic construction in convex geometry, see e.g. [Sch93]. The pointwise way of defining algebras over subsets (carriers of subalgebras) has also been studied in universal algebra, see e.g. [BM07, BM03, Bri93].

Next, we define $\mathcal{P}_c$ on arrows. For a convex homomorphism $h \colon \mathbb{A} \to \mathbb{B}$, $\mathcal{P}_c h = \mathcal{P}h$. The following property ensures that we are on the right track.

Proposition 5.1. *$\mathcal{P}_c\mathbb{A}$ is a convex algebra. If $h \colon \mathbb{A} \to \mathbb{B}$ is a convex homomorphism, then so is $\mathcal{P}_c h \colon \mathcal{P}_c\mathbb{A} \to \mathcal{P}_c\mathbb{B}$. $\mathcal{P}_c$ is a functor on $\mathrm{EM}(\mathcal{D})$.*

Proof. Due to Proposition 3.3, to prove that $\mathcal{P}_c\mathbb{A}$ is a convex algebra, all we need is to check (1) idempotence, (2) parametric commutativity, and (3) parametric associativity.

(1) $C \subseteq pC + \bar{p}C$ as $c = pc + \bar{p}c \in pC + \bar{p}C$. For the oposite inclusion, consider $pc_1 + \bar{p}c_2 \in pC + \bar{p}C$ for $c_1, c_2 \in C$. As C is convex, $pc_1 + \bar{p}c_2 \in C$. Hence idempotence holds.
(2) Follows from parametric commutativity in $\mathbb{A}$. We have

$$pC + \bar{p}D = \{pc + \bar{p}d \mid c \in C, d \in D\} = \{\bar{p}d + pc \mid d \in D, c \in C\} = \bar{p}D + pC$$

proving parametric commutativity.
(3) Similarly, parametric associativity follows from parametric associativity in $\mathbb{A}$:

$$
\begin{aligned}
p(qC + \bar{q}D) + \bar{p}E &= \{p(qc + \bar{q}d) + \bar{p}e \mid c \in C, d \in D, e \in E\} \\
&= \left\{pqc + \overline{pq}\left(\frac{p\bar{q}}{\overline{pq}}d + \frac{\bar{p}}{\overline{pq}}e\right) \mid c \in C, d \in D, e \in E\right\} \\
&= pqC + \overline{pq}\left(\frac{p\bar{q}}{\overline{pq}}D + \frac{\bar{p}}{\overline{pq}}E\right).
\end{aligned}
$$

Furthermore, we have, straightforwardly,

$$
\begin{aligned}
\mathcal{P}_c h(pC + \bar{p}D) &= h(pC + \bar{p}D) \\
&= h(\{pc + \bar{p}d \mid c \in C, d \in D\}) \\
&= \{h(pc + \bar{p}d) \mid c \in C, d \in D\} \\
&= \{ph(c) + \bar{p}h(d) \mid c \in C, d \in D\} \\
&= ph(C) + \bar{p}h(D) \\
&= p\mathcal{P}_c h(C) + \bar{p}\mathcal{P}_c h(D).
\end{aligned}
$$

Proposition 4.6 now implies the property. $\qquad\square$

Remark 5.2. $\mathcal{P}_c$ is not a lifting of C to $\mathrm{EM}(\mathcal{D})$, but it holds that $C = \mathcal{U} \circ \mathcal{P}_c \circ \mathcal{F}$ as illustrated below on the left. $\mathcal{P}_c$ is also not a lifting of $\mathcal{P}_{ne}$, the nonempty powerset functor,

but we have an embedding natural transformation $e\colon \mathcal{U}\circ \mathcal{P}_{\mathrm{c}} \Rightarrow \mathcal{P}_{ne}\circ \mathcal{U}$ given by $e(C) = C$, i.e., we are in the situation:

$$
\begin{array}{ccc}
\mathrm{EM}(\mathcal{D}) \xrightarrow{\ \mathcal{P}_{\mathrm{c}}\ } \mathrm{EM}(\mathcal{D}) & \qquad & \mathrm{EM}(\mathcal{D}) \xrightarrow{\ \mathcal{P}_{\mathrm{c}}\ } \mathrm{EM}(\mathcal{D}) \\
\mathcal{F}\uparrow \qquad \downarrow \mathcal{U} & & \mathcal{U}\downarrow \quad \supseteq \quad \downarrow \mathcal{U} \\
\mathbf{Sets} \xrightarrow{\ C\ } \mathbf{Sets} & & \mathbf{Sets} \xrightarrow{\ \mathcal{P}_{ne}\ } \mathbf{Sets}
\end{array}
$$

The right diagram in Remark 5.2 simply states that every convex subset is a subset, but this fact and the natural transformation e are useful in the sequel. In particular, using e we can show the next result.

Proposition 5.3. $\mathcal{P}_{\mathrm{c}}$ *is a monad on* $\mathrm{EM}(\mathcal{D})$*, with* η *and* μ *as for the powerset monad.*

Proof. Let $\mathbb{X}$ be a convex algebra and consider $\mathcal{P}_{\mathrm{c}}\mathbb{X}$. We have $\eta(x) = \{x\}$ is a convex subset, as every singleton is. Moreover, η is a convex homomorphism as $p\{x\} + \bar{p}\{y\} = \{px + \bar{p}y\}$. We have η (of $\mathcal{P}_{\mathrm{c}}$) is natural if and only if the upper square of the left diagram below commutes.

$$
\begin{array}{ccc}
\mathcal{U}\mathbb{X} \xrightarrow{\ \mathcal{U}f\ } \mathcal{U}\mathbb{Y} & \qquad & \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathcal{P}_{\mathrm{c}}\mathbb{X} \xrightarrow{\ \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathcal{P}_{\mathrm{c}}f\ } \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathcal{P}_{\mathrm{c}}\mathbb{Y} \\
\eta_{\mathbb{X}}\downarrow \qquad \downarrow\eta_{\mathbb{Y}} & & \mu_{\mathbb{X}}\downarrow \qquad \downarrow\mu_{\mathbb{Y}} \\
\eta_X\left(\ \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathbb{X} \xrightarrow{\ \mathcal{U}\mathcal{P}_{\mathrm{c}}f\ } \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathbb{Y}\ \right)\eta_Y & & \mu_X\left(\ \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathbb{X} \xrightarrow{\ \mathcal{U}\mathcal{P}_{\mathrm{c}}f\ } \mathcal{U}\mathcal{P}_{\mathrm{c}}\mathbb{Y}\ \right)\mu_Y \\
e_{\mathbb{X}}\downarrow \qquad \downarrow e_{\mathbb{Y}} & & e_{\mathbb{X}}\downarrow \qquad \downarrow e_{\mathbb{Y}} \\
\mathcal{P}\mathcal{U}\mathbb{X} \xrightarrow{\ \mathcal{P}\mathcal{U}f\ } \mathcal{P}\mathcal{U}\mathbb{Y} & & \mathcal{P}\mathcal{U}\mathbb{X} \xrightarrow{\ \mathcal{P}\mathcal{U}f\ } \mathcal{P}\mathcal{U}\mathbb{Y}
\end{array}
$$

However, the outer square of the diagram does commute - due to naturality of η (of $\mathcal{P}$), the lower square does commute - due to naturality of e, the outside triangles also do - due to the definitions of both η's and e, and e is injective. As a consequence, the upper square commutes as well.

For μ, notice that also $\mu_{\mathbb{X}}$ is a convex homomorphism from $\mathcal{P}_{\mathrm{c}}\mathcal{P}_{\mathrm{c}}\mathbb{X}$ to $\mathcal{P}_{\mathrm{c}}\mathbb{X}$, and all the arguments that we used for naturality of η apply to the naturality of μ (of $\mathcal{P}_{\mathrm{c}}$) as well, when looking at the right diagram above. So, μ is natural as well.

Clearly, η and μ (of $\mathcal{P}_{\mathrm{c}}$) satisfy the compatibility conditions of the definition of a monad, as so do η and μ (of $\mathcal{P}$). ☐

5.2. Termination on Convex Algebras.

The functor $\mathcal{P}_{\mathrm{c}}$ defined in the previous section allows only for nonempty convex subsets. We still miss a way to express termination. The question of termination amounts to the question of extending a convex algebra $\mathbb{A}$ with a single element $*$. This question turns out to be rather involved, beyond the scope of this paper. The answer from [SW18] is: there are many ways to extend any convex algebra $\mathbb{A}$ with a single element, but there is only one natural functorial way. Somehow now mathematics is forcing us the choice of a specific computational behaviour for termination!

Given a convex algebra $\mathbb{A}$, let $\mathbb{A} + 1$ have the carrier $A + \{*\}$ for $* \notin A$ and convex operations given by

$$
px \oplus \bar{p}y = \begin{cases} px + \bar{p}y\,, & x, y \in A, \\ * & , \quad x = * \text{ or } y = *. \end{cases} \tag{5.1}
$$

Here, the newly added $*$ behaves as a black hole that attracts every other element of the algebra in a convex combination. It is worth to remark that this extension is folklore [Fri15].

Proposition 5.4 ([SW18, Fri15]). $\mathbb{A}+1$ *as defined above is a convex algebra that extends* $\mathbb{A}$ *by a single element. The map* $h+1$ *obtained with the termination functor in* **Sets** *is a convex homomorphism if* $h\colon \mathbb{A} \to \mathbb{B}$ *is. The assignments* $(-)+1$ *give a functor on* $\mathrm{EM}(\mathcal{D})$. $\qquad\square$

We call the functor $(-)+1$ on $\mathrm{EM}(\mathcal{D})$ the termination functor, due to the following.

Lemma 5.5. *The functor* $(-)+1$ *is a lifting of the termination functor to* $\mathrm{EM}(\mathcal{D})$. $\qquad\square$

Remark 5.6. Note that we are abusing notation here: Our termination functor $(-)+1$ on $\mathrm{EM}(\mathcal{D})$ is not the coproduct $(-)+1$ in $\mathrm{EM}(\mathcal{D})$. The coproduct was concretely described in [JWW15, Lemma 4], and the coproduct $\mathbb{X}+1$ has a much larger carrier than $X+1$. Nevertheless, we use the same notation as it is very intuitive and due to Lemma 5.5.

5.3. Constant Exponent on Convex Algebras.

We now show the existence of a constant exponent functor on $\mathrm{EM}(\mathcal{D})$. Let L be a set of labels or actions. Let $\mathbb{A}$ be a convex algebra. Consider $\mathbb{A}^L$ with carrier $A^L = \{f \mid f\colon L \to A\}$ and operations defined (pointwise) by $(pf + \bar{p}g)(l) = pf(l) + \bar{p}g(l)$.

The following property follows directly from the definitions.

Proposition 5.7. $\mathbb{A}^L$ *is a convex algebra. If* $h\colon \mathbb{A} \to \mathbb{B}$ *is a convex homomorphism, then so is* $h^L\colon \mathbb{A}^L \to \mathbb{B}^L$ *defined as in* **Sets**. *Hence,* $(-)^L$ *defined above is a functor on* $\mathrm{EM}(\mathcal{D})$. $\quad\square$

We call $(-)^L$ the constant exponent functor on $\mathrm{EM}(\mathcal{D})$. The name and the notation is justified by the following (obvious) property.

Lemma 5.8. *The constant exponent* $(-)^L$ *on* $\mathrm{EM}(\mathcal{D})$ *is a lifting of the constant exponent functor* $(-)^L$ *on* **Sets**. $\qquad\square$

Example 5.9. Consider a free algebra $\mathcal{F}S = (\mathcal{D}S, \mu)$ of distributions over the set S. By applying first the functor $\mathcal{P}_\mathrm{c}$, then $(-)+1$ and then $(-)^L$, one obtains the algebra

$$(\mathcal{P}_\mathrm{c}\mathcal{F}S + 1)^L = \begin{pmatrix} \mathcal{D}\left((CS+1)^L\right) \\ \downarrow \alpha \\ (CS+1)^L \end{pmatrix}$$

where CS is the set of non-empty convex subsets of distributions over S, and α corresponds to the convex operations[3] $\sum p_i f_i$ defined by

$$\left(\sum p_i f_i\right)(l) = \begin{cases} \{\sum p_i \xi_i \mid \xi_i \in f_i(l)\} & f_i(l) \in CS \text{ for all } i \in \{1,\ldots,n\} \\ * & f_i(l) = * \text{ for some } i \in \{1,\ldots,n\} \end{cases}$$

5.4. Transition Systems on Convex Algebras.

We now compose the three functors introduced above to properly model transition systems as coalgebras on $\mathrm{EM}(\mathcal{D})$. The functor that we are interested in is $(\mathcal{P}_\mathrm{c}+1)^L\colon \mathrm{EM}(\mathcal{D}) \to \mathrm{EM}(\mathcal{D})$. A coalgebra $(\mathbb{S}, c)$ for this functor can be thought of as a transition system with labels in L where the state space carries a convex algebra and the transition function $c\colon \mathbb{S} \to (\mathcal{P}_\mathrm{c}\mathbb{S}+1)^L$ is a homomorphism of convex algebras. This property entails compositionality: the transitions of a composite state $px_1 + \bar{p}x_2$ are fully determined by the transitions of its components x_1 and x_2, as shown in the next proposition. We write $x \overset{a}{\mapsto} y$ for $x, y \in S$, the carrier of $\mathbb{S}$ if $y \in c(x)(a)$, and $x \overset{a}{\not\mapsto}$ if $c(x)(a) = *$.

---

[3]In this case, for future reference, it is convenient to spell out the n-ary convex operations.

Proposition 5.10. *Let $(\mathbb{S}, c)$ be a $(\mathcal{P}_c + 1)^L$-coalgebra, and let x_1, x_2, y_1, y_2, z be elements of S, the carrier of $\mathbb{S}$. Then, for all $p \in (0,1)$, and $a \in L$*

- $px_1 + \bar{p}x_2 \overset{a}{\mapsto} z$ *iff* $z = py_1 + \bar{p}y_2$, $x_1 \overset{a}{\mapsto} y_1$ *and* $x_2 \overset{a}{\mapsto} y_2$;
- $px_1 + \bar{p}x_2 \overset{a}{\not\mapsto}$ *iff* $x_1 \overset{a}{\not\mapsto} y_1$ *or* $x_2 \overset{a}{\not\mapsto} y_2$.

Proof. Since c is a convex algebra homomorphism, we have that for all $p \in (0,1)$ and $a \in L$, $c(px_1 + \bar{p}x_2)(a) = (pc(x_1) + \bar{p}c(x_2))(a)$. The latter is equal, by definition of $(-)^L$ (see Section 5.3), to $pc(x_1)(a) + \bar{p}c(x_2)(a)$. If there is $i \in \{1, 2\}$ such that $c(x_i)(a) = *$, then $pc(x_1)(a) + \bar{p}c(x_2)(a) = *$ (see Section 5.2). If not, then both $c(x_1)(a)$ and $c(x_2)(a)$ are in $\mathcal{P}_c\mathbb{S}$: $pc(x_1)(a) + \bar{p}c(x_2)(a)$ is by definition (see Section 5.1) the set $\{py_1 + \bar{p}y_2 \mid y_1 \in c(x_1)(a) \text{ and } y_2 \in c(x_2)(a)\}$. $\qquad\square$

Example 5.11. Consider the PA in Figure 1 (left) and the belief-state transformer generated by it (right). We have $\frac{1}{2}y_1 + \frac{1}{2}y_2 \overset{a}{\mapsto} \frac{1}{4}y_1 + \frac{3}{4}y_2$ since $y_1 \overset{a}{\mapsto} \frac{1}{2}y_1 + \frac{1}{2}y_2$ and $y_2 \overset{a}{\mapsto} y_2$ and

$$\frac{1}{2}\left(\frac{1}{2}y_1 + \frac{1}{2}y_2\right) + \frac{1}{2}y_2 = \frac{1}{4}y_1 + \frac{3}{4}y_2.$$

Every transition of $\frac{1}{2}y_1 + \frac{1}{2}y_2$ arises in this way.

Transition systems on convex algebras are the bridge between PA and LTSs. In the next section we will show that one can transform an arbitrary PA into a $(\mathcal{P}_c + 1)^L$-coalgebra and that, in the latter, behavioural equivalence coincides with the standard notion of bisimilarity for LTSs (Proposition 6.4).

6. From PA to Belief-State Transformers

Before turning our attention to PA, it is worth to make a further step of abstraction.

Recall from Remark 5.2 how $\mathcal{P}_c$ is related to C and $\mathcal{P}_{ne}$. The following definition is the obvious generalisation.

Definition 6.1. Let $\mathcal{M} \colon \mathbf{Sets} \to \mathbf{Sets}$ be a monad with $\mathcal{M} = \mathcal{U} \circ \mathcal{F}$ and $\mathcal{L}_1, \mathcal{L}_2 \colon \mathbf{Sets} \to \mathbf{Sets}$ be two functors. A functor $\mathcal{H} \colon \mathrm{EM}(\mathcal{M}) \to \mathrm{EM}(\mathcal{M})$ is

- a *quasi lifting* of $\mathcal{L}_1$ if the diagram on the left commutes.
- a *lax lifting* of $\mathcal{L}_2$ if there exists an injective natural transformation $e \colon \mathcal{U} \circ \mathcal{H} \Rightarrow \mathcal{L}_2 \circ \mathcal{U}$ as depicted on the right.
- an $(\mathcal{L}_1, \mathcal{L}_2)$ *quasi-lax lifting* if it is both a quasi lifting of $\mathcal{L}_1$ and a lax lifting of $\mathcal{L}_2$.

$$
\begin{array}{ccc}
\mathrm{EM}(\mathcal{M}) \xrightarrow{\ \mathcal{H}\ } \mathrm{EM}(\mathcal{M}) & \qquad & \mathrm{EM}(\mathcal{M}) \xrightarrow{\ \mathcal{H}\ } \mathrm{EM}(\mathcal{M}) \\
\mathcal{F}\uparrow \qquad\qquad \downarrow\mathcal{U} & & \mathcal{U}\downarrow \qquad \swarrow \qquad \downarrow\mathcal{U} \\
\mathbf{Sets} \xrightarrow{\ \mathcal{L}_1\ } \mathbf{Sets} & & \mathbf{Sets} \xrightarrow{\ \mathcal{L}_2\ } \mathbf{Sets}
\end{array} \qquad \diamond
$$

So, for instance, $\mathcal{P}_c$ is a $(C, \mathcal{P}_{ne})$ quasi-lax lifting by Remark 5.2. From this fact, it follows that $(\mathcal{P}_c + 1)^L$ is a $((C + 1)^L, (\mathcal{P}_{ne} + 1)^L)$ quasi-lax lifting. Another interesting example is the generalised determinisation (Section 4.2): it is easy to see that $\overline{F}$ is a $(F\mathcal{M}, F)$-quasi-lax lifting. Indeed, like in the generalised powerset construction, one can

construct the following functors.

$$\mathrm{Coalg}_{\mathrm{EM}(\mathcal{M})}\,(\mathcal{H})$$

$$\mathrm{Coalg}_{\mathbf{Sets}}\,(\mathcal{L}_1) \xrightarrow{\overline{\mathcal{F}}} \qquad \xrightarrow{\overline{\mathcal{U}}} \mathrm{Coalg}_{\mathbf{Sets}}\,(\mathcal{L}_2)$$

We first define $\overline{\mathcal{F}}$. Take an $\mathcal{L}_1$-coalgebra (S, c) and recall that $\mathcal{F}S$ is the free algebra $\mu\colon \mathcal{M}\mathcal{M}S \to \mathcal{M}S$. The left diagram in Definition 6.1 entails that $\mathcal{H}\mathcal{F}S$ is an algebra $\alpha\colon \mathcal{M}\mathcal{L}_1 S \to \mathcal{L}_1 S$. We call $\mathcal{U}c^{\sharp}$ the composition $\mathcal{U}\mathcal{F}S = \mathcal{M}S \xrightarrow{\mathcal{M}c} \mathcal{M}\mathcal{L}_1 S \xrightarrow{\alpha} \mathcal{L}_1 S = \mathcal{U}\mathcal{H}\mathcal{F}S$. The next lemma shows that $c^{\sharp}\colon \mathcal{F}S \to \mathcal{H}\mathcal{F}S$ is a map in $\mathrm{EM}(\mathcal{M})$.

Lemma 6.2. *There is a 1-1 correspondence between $\mathcal{L}_1$-coalgebras on $\mathbf{Sets}$ and $\mathcal{H}$-coalgebras on $\mathrm{EM}(\mathcal{M})$ with carriers free algebras, if $\mathcal{H}$ is a quasi lifting of $\mathcal{L}_1$:*

$$\frac{c\colon S \to \mathcal{L}_1 S \quad in \quad \mathbf{Sets}}{c^{\#}\colon \mathcal{F}S \to \mathcal{H}\mathcal{F}S \quad in \quad \mathrm{EM}(\mathcal{M})}$$

- *given c, we have $\mathcal{U}c^{\#} = \alpha \circ \mathcal{M}c$ for $\alpha = \mathcal{H}\mathcal{F}S$,*
- *given $c^{\#}$, we have $c = \mathcal{U}c^{\#} \circ \eta$.*

The assignment $\overline{\mathcal{F}}(S, c) = (\mathcal{F}S, c^{\#})$ and $\overline{\mathcal{F}}(h) = \mathcal{M}h$ gives a functor $\overline{\mathcal{F}}\colon \mathrm{Coalg}_{\mathbf{Sets}}\,(\mathcal{L}_1) \to \mathrm{Coalg}_{\mathrm{EM}(\mathcal{M})}\,(\mathcal{H})$.

Proof. First, given c, consider the map $\alpha \circ \mathcal{M}c$. We need to show that $\alpha \circ \mathcal{M}c$ is an algebra homomorphism from the free algebra $\mathcal{F}S$ to $H\mathcal{F}S$ in $\mathrm{EM}(\mathcal{M})$. This will show that $c^{\#}\colon \mathcal{F}S \to H\mathcal{F}S$ and $\mathcal{U}c^{\#} = \alpha \circ \mathcal{M}c$.

Note that

$$\begin{pmatrix} \mathcal{M}\mathcal{L}_1 S \\ \downarrow^{\alpha} \\ \mathcal{L}_1 S \end{pmatrix} = \mathcal{H} \begin{pmatrix} \mathcal{M}\mathcal{M}S \\ \downarrow^{\mu} \\ \mathcal{M}S \end{pmatrix}.$$

The needed homomorphism property holds since the following diagram commutes:

$$\begin{array}{ccccc} \mathcal{M}\mathcal{M}S & \xrightarrow{\mathcal{M}\mathcal{M}c} & \mathcal{M}\mathcal{M}\mathcal{L}_1 S & \xrightarrow{\mathcal{M}\alpha} & \mathcal{M}\mathcal{L}_1 S \\ \downarrow^{\mu} & & \downarrow^{\mu} & & \downarrow^{\alpha} \\ \mathcal{M}S & \xrightarrow{\mathcal{M}c} & \mathcal{M}\mathcal{L}_1 S & \xrightarrow{\alpha} & \mathcal{L}_1 S \end{array}$$

as the left square commutes by the naturality of μ and the right one by the Eilenberg-Moore law for α.

Next, we show that the assignments $c \overset{\triangleright}{\mapsto} c^{\#}$ and $c^{\#} \overset{\triangleleft}{\mapsto} c$ are inverse to each other.

We have $\triangleleft \circ \triangleright(c) = c$ as $\alpha \circ \mathcal{M}c \circ \eta \overset{\mathrm{nat.}\eta}{=} \alpha \circ \eta \circ c \overset{\mathrm{EM-law}}{=} c$. Also, we have $\triangleright \circ \triangleleft(c^{\#}) = c^{\#}$ as

$$\begin{aligned} \alpha \circ \mathcal{M}(\mathcal{U}c^{\#} \circ \eta) &= \alpha \circ \mathcal{M}\mathcal{U}c^{\#} \circ \mathcal{M}\eta \\ &\overset{(*)}{=} \mathcal{U}c^{\#} \circ \mu \circ \mathcal{M}\eta \\ &\overset{(**)}{=} \mathcal{U}c^{\#} \end{aligned}$$

where the equality marked by $(*)$ holds since $\mathcal{U}c^{\#}$ is an algebra homomorphism, proven above, and the equality marked by $(**)$ holds by the monad law.

By the above, $\overline{\mathcal{F}}$ is well defined on objects. It remains to prove that for two $\mathcal{L}_1$-coalgebras on $\mathbf{Sets}$ (S, c_S) and (T, c_T), and a coalgebra homomorphism $h\colon (S, c_S) \to (T, c_T)$ with

$c_T \circ h = \mathcal{L}_1 h \circ c_S$ we have that $\mathcal{M}h$ is a coalgebra homomorphism in $\mathrm{EM}(\mathcal{M})$ from $(\mathcal{F}S, c_S^{\#})$ to $(\mathcal{F}T, c_T^{\#})$.

We have

where the outer triangles commute by definition; the upper square commutes by assumption, i.e., since h is a homomorphism and $\mathcal{U}$ and $\mathcal{F}$ are functors; and the lower square simply states that $\mathcal{H}\mathcal{F}h$ is an arrow in $\mathrm{EM}(\mathcal{M})$ which of course holds as $\mathcal{H}$ and $\mathcal{F}$ are functors. $\qquad\square$

Now we can define $\overline{\mathcal{U}}\colon \mathrm{Coalg}_{\mathrm{EM}(\mathcal{M})}(\mathcal{H}) \to \mathrm{Coalg}_{\mathbf{Sets}}(\mathcal{L}_2)$ as mapping every coalgebra $(\mathbb{S}, c)$ with $c\colon \mathbb{S} \to \mathcal{H}\mathbb{S}$ into

$$\overline{\mathcal{U}}(\mathbb{S}, c) = (\mathcal{U}\mathbb{S}, e_{\mathbb{S}} \circ \mathcal{U}c) \text{ where } \mathcal{U}\mathbb{S} \xrightarrow{\mathcal{U}c} \mathcal{U}\mathcal{H}\mathbb{S} \xrightarrow{e_{\mathbb{S}}} \mathcal{L}_2\mathcal{U}\mathbb{S}$$

and every coalgebra homomorphism $h\colon (\mathbb{S}, c) \to (\mathbb{T}, d)$ into $\overline{\mathcal{U}}h = \mathcal{U}h$. Routine computations confirm that $\overline{\mathcal{U}}$ is a functor.

Since $\overline{\mathcal{U}}$ is a functor that keeps the state set constant and is identity on morphisms, every kernel bisimulation on $(\mathbb{S}, c)$ is also a kernel bisimulation on $\overline{\mathcal{U}}(\mathbb{S}, c)$. The converse is not true in general: a kernel bisimulation R on $\overline{\mathcal{U}}(\mathbb{S}, c)$ is a kernel bisimulation on $(\mathbb{S}, c)$ only if it is a *congruence* with respect to the algebraic structure of $\mathbb{S}$.

Formally, R is a congruence if and only if the set $\mathcal{U}\mathbb{S}/R$ of equivalence classes of R carries an Eilenberg-Moore algebra and the function $\mathcal{U}[-]_R\colon \mathcal{U}\mathbb{S} \to \mathcal{U}\mathbb{S}/R$ mapping every element of $\mathcal{U}\mathbb{S}$ to its R-equivalence class is an algebra homomorphism.

Proposition 6.3. *The following are equivalent:*
- *R is a kernel bisimulation on $(\mathbb{S}, c)$,*
- *R is a congruence of $\mathbb{S}$ and a kernel bisimulation of $\overline{\mathcal{U}}(\mathbb{S}, c)$.*
Proof. We already discussed above that if R is a kernel bisimulation on $(\mathbb{S}, c)$, then it is a kernel bisimulation of $\overline{\mathcal{U}}(\mathbb{S}, c)$. Moreover, any kernel bisimulation of a coalgebra carried by an algebra is a congruence, as kernels of algebra homomorphisms are congruences.

For the other implication, assume that R is a congruence and a kernel bisimulation of $\overline{\mathcal{U}}(\mathbb{S}, c)$. Then $\mathcal{U}\mathbb{S}/R$ carries an $\mathcal{M}$-algebra, denoted by $\mathbb{S}/R$, and $[-]_R\colon \mathbb{S} \to \mathbb{S}/R$ is a map in $\mathrm{EM}(\mathcal{M})$. If R is a kernel bisimulation on $\overline{\mathcal{U}}(\mathbb{S}, c)$, then there exists a function $f\colon \mathcal{U}(\mathbb{S}/R) \to \mathcal{L}_2\mathcal{U}(\mathbb{S}/R)$ such that the outer square in the diagram below on the left commutes.
The bottom square commutes by naturality of e. The function c_R is obtained by the epi-mono factorisation structure on **Sets** as shown on the right. To conclude that R is a kernel bisimulation on $(\mathbb{S}, c)$, one only needs to show that c_R is a map in $\mathrm{EM}(\mathcal{M})$.

Let $\alpha\colon \mathcal{M}\mathcal{U}\mathbb{S} \to \mathcal{U}\mathbb{S}$ denote the algebra structure of $\mathbb{S}$, that is $\mathbb{S} = (\mathcal{U}\mathbb{S}, \alpha)$. Similarly $\mathbb{S}/R = (\mathcal{U}(\mathbb{S}/R), \alpha_R)$, $\mathcal{H}\mathbb{S} = (\mathcal{U}\mathcal{H}\mathbb{S}, \alpha_H)$ and $\mathcal{H}(\mathbb{S}/R) = (\mathcal{U}\mathcal{H}(\mathbb{S}/R), \alpha_{RH})$.

Consider the above cube on **Sets**. The front face commutes by construction of c_R. The back face commutes as it is just $\mathcal{M}$ applied to the front face. The top face commutes because R is a congruence: the map $[-]_R\colon (\mathcal{U}\mathbb{S}, \alpha) \to (\mathcal{U}(\mathbb{S}/R), \alpha_R)$ is an $\mathcal{M}$-algebra homomorphism. Since $\mathcal{H}$ is a functor also $\mathcal{H}[-]_R\colon \mathcal{H}(\mathcal{U}\mathbb{S}, \alpha) \to \mathcal{H}(\mathcal{U}(\mathbb{S}/R), \alpha_R)$ is an $\mathcal{M}$-algebra homomorphism: this means that also the bottom face commutes. The leftmost face commutes since, by assumption, c is a homomorphism of $\mathcal{M}$-algebras.

To prove that also c_R is a homomorphism of $\mathcal{M}$-algebras amounts to checking that also the rightmost face commutes. For this it is essential that $\mathcal{M}$ preserves epis, as every **Sets**-endofunctor does, so that $\mathcal{M}\mathcal{U}[-]_R$ is an epi. From this fact and the following derivation, we conclude that $c_R \circ \alpha_R = \alpha_{RH} \circ \mathcal{M}c_R$.

$$
\begin{aligned}
c_R \circ \alpha_R \circ \mathcal{M}\mathcal{U}[-]_R &= c_R \circ \mathcal{U}[-]_R \circ \alpha \\
&= \mathcal{U}\mathcal{H}[-]_R \circ \mathcal{U}c \circ \alpha \\
&= \mathcal{U}\mathcal{H}[-]_R \circ \alpha_H \circ \mathcal{M}\mathcal{U}c \\
&= \alpha_{RH} \circ \mathcal{M}\mathcal{U}\mathcal{H}[-]_R \circ \mathcal{M}\mathcal{U}c \\
&= \alpha_{RH} \circ \mathcal{M}c_R \circ \mathcal{M}\mathcal{U}[-]_R \quad \square
\end{aligned}
$$

$M = (S, L, \rightarrow)$	$M_c = (S, L, \rightarrow_c)$	$M_{bs} = (\mathcal{D}S, L, \mapsto)$
$(S, c_M \colon S \to (\mathcal{P}\mathcal{D})^L)$	$(S, \overline{c}_M \colon S \to (C+1)^L)$	$(\mathcal{D}S, \hat{c}_M \colon \mathcal{D}S \to (\mathcal{P}\mathcal{D}S)^L)$
(S, c_M)	$(S, \overline{c}_M) = \mathcal{T}_{\mathrm{conv}}(S, c_M)$	$(\mathcal{D}S, \hat{c}_M) = \overline{\mathcal{U}} \circ \overline{\mathcal{F}} \circ \mathcal{T}_{\mathrm{conv}}(S, c_M)$
c_M	$\overline{c}_M = \mathrm{conv}^L \circ c_M$	$\hat{c}_M = (e_{\mathcal{F}S} + 1)^L \circ \mathcal{U}\overline{c}_M^\sharp$

Table 1: The three PA models, their corresponding **Sets**-coalgebras, and relations to M.

In particular, Proposition 6.3, the fact that behavioural equivalence $\approx$ is a kernel bisimulation, and the following result ensure that the functor $\overline{\mathcal{U}} \colon \mathrm{Coalg}_{\mathrm{EM}(\mathcal{D})} \, (\mathcal{P}_c + 1)^L \to \mathrm{Coalg}_{\mathbf{Sets}} \, \mathcal{P}^L$ preserves and reflects $\approx$.

Proposition 6.4. *Let $(\mathbb{S}, c)$ be a $(\mathcal{P}_c + 1)^L$-coalgebra. Behavioural equivalence on $\overline{\mathcal{U}}(\mathbb{S}, c)$ is a convex congruence[4]. Hence, $\overline{\mathcal{U}}$ preserves and reflects behavioural equivalence.*

Proof. $\overline{\mathcal{U}}(\mathbb{S}, c)$ is a coalgebra for the functor $\mathcal{P}^L \colon \mathbf{Sets} \to \mathbf{Sets}$, namely a labeled transition system. It is well known that for these kind of coalgebras, behavioural equivalence ($\approx$) coincides with the standard notion of bisimilarity.

We can thus proceed by exploiting coinduction and prove that the following relation is a bisimulation (in the standard sense).

$$R = \{(p\zeta_1 + \overline{p}\xi_1, p\zeta_2 + \overline{p}\xi_2) \mid \zeta_1 \approx \zeta_2, \ \xi_1 \approx \xi_2 \text{ and } p \in [0, 1]\}$$

Suppose that $p\zeta_1 + \overline{p}\xi_1 \overset{a}{\mapsto} \epsilon_1$. Then, by Proposition 5.10, $\epsilon_1 = p\zeta_1' + \overline{p}\xi_1'$ with $\zeta_1 \overset{a}{\mapsto} \zeta_1'$ and $\xi_1 \overset{a}{\mapsto} \xi_1'$. Since $\zeta_1 \approx \zeta_2$ and $\xi_1 \approx \xi_2$, there exists $\zeta_2' \approx \zeta_1'$ and $\xi_2' \approx \xi_1'$ such that $\zeta_2 \overset{a}{\mapsto} \zeta_2'$ and $\xi_2 \overset{a}{\mapsto} \xi_2'$. Again, by Proposition 5.10, $p\zeta_2 + \overline{p}\xi_2 \overset{a}{\mapsto} p\zeta_2' + \overline{p}\xi_2'$. Moreover, by definition of R, $p\zeta_1' + \overline{p}\xi_1' \, R \, p\zeta_2' + \overline{p}\xi_2'$. $\qquad\square$

This means that $\approx$ for $(\mathcal{P}_c+1)^L$-coalgebras, called transition systems on convex algebras in Section 5.4, coincides with the standard notion of bisimilarity for LTSs.

Table 1 summarises all models of PA: from the classical model M being a $\mathcal{P}\mathcal{D}^L$-coalgebra (S, c_M) on **Sets**, via the convex model M_c obtained as $\mathcal{T}_{\mathrm{conv}}(S, c_M)$, to the belief state transformer M_{bs}. The latter coincides with $\overline{\mathcal{U}} \circ \overline{\mathcal{F}} \circ \mathcal{T}_{\mathrm{conv}}(S, c_M)$.

Theorem 6.5. *Let (S, c_M) be a probabilistic automaton. For all $\xi, \zeta \in \mathcal{D}S$,*
$$\xi \sim_d \zeta \quad \Leftrightarrow \quad \xi \approx \zeta \ \text{ in } \ \overline{\mathcal{U}} \circ \overline{\mathcal{F}} \circ \mathcal{T}_{\mathrm{conv}}(S, c_M).$$

Proof. We have that $\overline{\mathcal{U}} \circ \overline{\mathcal{F}} \circ \mathcal{T}_{\mathrm{conv}}(S, c_M) = (\mathcal{D}S, \hat{c}_M) = (\mathcal{D}S, (e_{\mathcal{F}S} + 1)^L \circ \mathcal{U}\overline{c}_M^\sharp)$. Since behavioural equivalence in $(\mathcal{D}S, (e_{\mathcal{F}S}+1)^L \circ \mathcal{U}\overline{c}_M^\sharp)$ is bisimilarity for LTSs, by Proposition 6.4, all that we need to show is that $(\mathcal{D}S, \hat{c}_M) = (\mathcal{D}S, (e_{\mathcal{F}S}+1)^L \circ \mathcal{U}\overline{c}_M^\sharp)$ is exactly the belief-state transformer M_{bs} induced by M, as announced by Table 1. Moreover, since $(e_{\mathcal{F}S} + 1)^L$ is the identity embedding, it suffices to understand $\mathcal{U}\overline{c}_M^\sharp$.

First, by definition, $\mathcal{T}_{\mathrm{conv}}(S, c_M) = (S, \overline{c}_M) = (S, \mathrm{conv}^L \circ c_M)$, and concretely,

$$s \overset{l}{\to}_c \xi \text{ in } M_c \text{ iff } \xi \in \overline{c}_M(s)(l) = \mathrm{conv}(c_M(s)(l)).$$

---

[4]Convex congruences are congruences of convex algebras, see e.g. [SW15]. They are convex equivalences, i.e., closed under componentwise-defined convex combinations.

Then $\mathcal{U}\bar{c}_M^\sharp = \alpha \circ \mathcal{D}\bar{c}_M \colon \mathcal{D}S \to \mathcal{D}((CS+1)^L) \to (CS+1)^L$ by Lemma 6.2, where α is the algebra structure from Example 5.9. Concretely, we have, for a distribution[5] $[s_i \mapsto p_i]$

$$
\begin{aligned}
\mathcal{U}\bar{c}_M^\sharp([s_i \mapsto p_i])(l) &= \alpha \circ \mathcal{D}\bar{c}_M([s_i \mapsto p_i])(l) \\
&= \alpha(\mathcal{D}\bar{c}_M([s_i \mapsto p_i])(l)) \\
&= \alpha([\bar{c}_M(s_i) \mapsto p_i])(l) \\
&= (*)
\end{aligned}
$$

Now $[\bar{c}_M(s_i) \mapsto p_i]$ is the distribution that assigns probability p_i to the function $l \mapsto \{\xi_i \mid s_i \xrightarrow{l}_c \xi_i\}$ if $s_i \xrightarrow{l}_c$, and $l \mapsto *$ otherwise. Hence, by the convex operations corresponding to the algebra structure α from Example 5.9 we have

$$
\begin{aligned}
(*) &= \begin{cases} \sum p_i\{\xi_i \mid s_i \xrightarrow{l}_c \xi_i\}) , & \forall i.\, s_i \xrightarrow{l}_c \\ * , & \exists i.\, s_i \not\xrightarrow{l}_c \end{cases} \\[2ex]
&= \begin{cases} \{\sum p_i\xi_i \mid s_i \xrightarrow{l}_c \xi_i\}) , & \forall i.\, s_i \xrightarrow{l}_c \\ * , & \exists i.\, s_i \not\xrightarrow{l}_c \end{cases}
\end{aligned}
$$

which means[6] that $\sum p_i s_i = [s_i \mapsto p_i] \xrightarrow{l} \sum p_i \xi_i$ in $(\mathcal{D}S, \hat{c}_M)$ whenever $s_i \xrightarrow{l}_c \xi_i$ which is exactly the same condition as $\sum p_i s_i \xrightarrow{l} \sum p_i \xi_i$ in M_{bs}. This completes the proof that M_{bs} is exactly the coalgebra $(\mathcal{D}S, \hat{c}_M)$. $\qquad\square$

Hence, distribution bisimilarity is indeed behavioural equivalence on the belief-state transformer and it coincides with standard bisimilarity.

7. Bisimulations Up-To Convex Hull

As we mentioned in Section 4.2, the generalised determinisation allows for the use of up-to techniques [Mil89, PS11]. An important example is shown in [BP13]: given a non-deterministic automaton $c \colon S \to 2 \times \mathcal{P}(S)^L$, one can reason on its determinisation $\mathcal{U}c^\sharp \colon \mathcal{P}(S) \to 2 \times \mathcal{P}(S)^L$ up-to the algebraic structure carried by the state space $\mathcal{P}(S)$. Given a probabilistic automaton $(S, L, \to)$, we would like to exploit the algebraic structure carried by $\mathcal{D}(S)$ to prove properties of the corresponding belief states transformer $(\mathcal{D}(S), L, \mapsto)$. Unfortunately, the lack of a suitable distributive law [VW06] makes it impossible to reuse the abstract results in [BPPR14]. Fortunately, we can redo all the proofs by adapting the theory in [PS11] to the case of probabilistic automata.

Hereafter we fix a PA $M = (S, L, \to)$ and the corresponding belief states transformer $M_{bs} = (\mathcal{D}(S), L, \mapsto)$. We denote by $Rel_{\mathcal{D}(S)}$ the lattice of relations over $\mathcal{D}(S)$ and define the monotone function $\mathrm{b} \colon Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$ mapping every relation $R \in Rel_{\mathcal{D}(S)}$ into

$$
\begin{aligned}
\mathrm{b}(R) \;::=\; \{(\zeta_1, \zeta_2) \;\mid\; & \forall a \in L,\;\; \forall\zeta_1' \text{ s.t. } \zeta_1 \xrightarrow{a} \zeta_1',\, \exists\zeta_2' \text{ s.t. } \zeta_2 \xrightarrow{a} \zeta_2' \text{ and } (\zeta_1', \zeta_2') \in R, \\
& \forall\zeta_2' \text{ s.t. } \zeta_2 \xrightarrow{a} \zeta_2',\, \exists\zeta_1' \text{ s.t. } \zeta_1 \xrightarrow{a} \zeta_1' \text{ and } (\zeta_1', \zeta_2') \in R\}.
\end{aligned}
$$

A *bisimulation* is a relation R such that $R \subseteq \mathrm{b}(R)$. Observe that these are just regular bisimulations for labeled transition systems and that the greatest fixpoint of b coincides

---

[5]In order to avoid confusion between convex operations and distributions, for the moment we use this explicit notation for distributions.

[6]Coming back to the usual notation for distributions, as formal sums.

exactly with $\sim_d$. The *coinduction* principle informs us that to prove that $\zeta_1 \sim_d \zeta_2$ it is enough to exhibit a bisimulation R such that $(\zeta_1, \zeta_2) \in R$.

Example 7.1. Consider the PA in Figure 1 (left) and the belief-state transformer generated by it (right). It is easy to see that the (Dirac distributions of the) states x_2 and y_2 are in $\sim_d$: the relation $\{(x_2, y_2)\}$ is a bisimulation. Also $\{(x_3, y_3)\}$ is a bisimulation: both $x_3 \not\xrightarrow{a}$ and $y_3 \not\xrightarrow{a}$. More generally, for all $\zeta, \xi \in \mathcal{D}(S)$, $p, q \in [0, 1]$, $p\zeta + \bar{p}x_3 \sim_d q\xi + \bar{q}y_3$ since both

$$p\zeta + \bar{p}x_3 \not\xrightarrow{a} \quad \text{and} \quad q\xi + \bar{q}y_3 \not\xrightarrow{a} . \tag{7.1}$$

Proving that $x_0 \sim_d y_0$ is more complicated. We will show this in Example 7.5 but, for the time being, observe that one would need an infinite bisimulation containing the following pairs of states.

$$
\begin{array}{ccccccccc}
x_0 & \xrightarrow{a} & x_1 & \xrightarrow{a} & \frac{1}{2}x_1 + \frac{1}{2}x_2 & \xrightarrow{a} & \frac{1}{4}x_1 + \frac{3}{4}x_2 & \xrightarrow{a} & \ldots \\
\vdots & & \vdots & & \vdots & & \vdots & & \vdots \\
y_0 & \xrightarrow{a} & \frac{1}{2}y_1 + \frac{1}{2}y_2 & \xrightarrow{a} & \frac{1}{4}y_1 + \frac{3}{4}y_2 & \xrightarrow{a} & \frac{1}{8}y_1 + \frac{7}{8}y_2 & \xrightarrow{a} & \ldots
\end{array}
$$

Indeed, all the distributions depicted above have infinitely many possible choices for $\xrightarrow{a}$ but, whenever one of them executes a depicted transition, the corresponding distribution is forced, because of (7.1), to also choose the depicted transition.

An *up-to technique* is a monotone map $\mathsf{f} \colon Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$, while a *bisimulation up-to* f is a relation R such that $R \subseteq \mathsf{b}\,\mathsf{f}(R)$. An up-to technique f is said to be *sound* if, for all $R \in Rel_{\mathcal{D}(S)}$, $R \subseteq \mathsf{b}\,\mathsf{f}(R)$ entails that $R \subseteq \sim_d$. It is said to be *compatible* if $\mathsf{f}\,\mathsf{b}(R) \subseteq \mathsf{b}\,\mathsf{f}(R)$. In [PS11], it is shown that every compatible up-to technique is also sound.

Hereafter we consider the *convex hull* technique $\mathrm{conv} \colon Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$ mapping every relation $R \in Rel_{\mathcal{D}(S)}$ into its convex hull which, for the sake of clarity, is

$$\mathrm{conv}(R) = \{(p\zeta_1 + \bar{p}\xi_1, p\zeta_2 + \bar{p}\xi_2) \mid (\zeta_1, \zeta_2) \in R, (\xi_1, \xi_2) \in R \text{ and } p \in [0, 1]\}.$$

Proposition 7.2. conv *is compatible.*

Proof. Assume that $(\epsilon_1, \epsilon_2) \in \mathrm{conv}(b(R))$. By definition of conv there exist $p \in [0, 1]$, $\zeta_1, \xi_1, \zeta_2, \xi_2 \in \mathcal{D}(S)$ such that
(a) $\epsilon_1 = p\zeta_1 + \bar{p}\xi_1$, $\epsilon_2 = p\zeta_2 + \bar{p}\xi_2$,
(b) $(\zeta_1, \zeta_2) \in \mathsf{b}(R)$ and $(\xi_1, \xi_2) \in \mathsf{b}(R)$.

To prove that $(\epsilon_1, \epsilon_2) \in \mathsf{b}(\mathrm{conv}(R))$, assume that $\epsilon_1 \xrightarrow{a} \epsilon_1'$ for some $a \in A$ and $\epsilon_1' \in \mathcal{D}(S)$. Then, by (a) and Proposition 5.10, $\zeta_1 \xrightarrow{a} \zeta_1'$ and $\xi_1 \xrightarrow{a} \xi_1'$ and $\epsilon_1' = p\zeta_1' + \bar{p}\xi_1'$. By (b), there exist $\zeta_2', \xi_2' \in \mathcal{D}(S)$ such that
(c) $\zeta_2 \xrightarrow{a} \zeta_2'$, $\xi_2 \xrightarrow{a} \xi_2'$ and
(d) $(\zeta_1', \zeta_2') \in R$, $(\xi_1', \xi_2') \in R$.

From (c) and Proposition 5.10, it follows that $\epsilon_2 \xrightarrow{a} p\zeta_2' + \bar{p}\xi_2'$. From (d), one obtains that $(\epsilon_1' = p\zeta_1' + \bar{p}\xi_1', p\zeta_2' + \bar{p}\xi_2') \in \mathrm{conv}(R)$.

One can proceed symmetrically for $\epsilon_2 \xrightarrow{a} \epsilon_2'$.

Therefore, by definition of b, $(\epsilon_1, \epsilon_2) \in \mathsf{b}(\mathrm{conv}(R))$. $\square$

This result has two consequences: First, conv is sound[7] and thus one can prove $\sim_d$ by means of bisimulation up-to conv; Second, conv can be effectively combined with other compatible up-to techniques [PS11]. In particular, by combining conv with up-to equivalence – which is well known to be compatible – one obtains up-to congruence cgr: $Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$. This technique maps a relation R into its congruence closure: the smallest relation containing R which is a congruence.

Proposition 7.3. cgr *is compatible.*

The proof of Proposition 7.3 can be elegantly presented using the modular approach developed in [PS11] that we recall hereafter.

Up-to techniques can be combined in a number of interesting ways. For a map f: $Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$, the *n*-iteration of f is defined as $f^{n+1} = f \circ f^n$ and $f^0 = id$, the identity function. The omega iteration is defined as $f^\omega(R) = \bigcup_{i=0}^{\infty} f^i(R)$. The following result from [PS11] informs us that compatible up-to techniques can be composed resulting in other compatible techniques.

Lemma 7.4. *The following functions are compatible:*
- id*: the identity function;*
- f $\circ$ g*: the composition of compatible functions* f *and* g*;*
- $\bigcup F$*: the pointwise union of an arbitrary family F of compatible functions:* $\bigcup F(R) = \bigcup_{f \in F} f(R)$*;*
- f^ω*: the (omega) iteration of a compatible function* f*, defined as* $f^\omega(R) = \bigcup_{i=0}^{\infty} f^i(R)$

$\square$

Apart from conv, we are interested in the following up-to techniques.
- the constant function r mapping every R into the identity relation $Id \subseteq \mathcal{D}(S) \times \mathcal{D}(S)$;
- the square function t mapping every R into $t(R) = R^2 = \{(\zeta_1, \zeta_3) \mid \exists \zeta_2. \ \zeta_1 R \zeta_2 R \zeta_3\}$;
- the opposite function s mapping every R into its opposite relation R^{-1}.

It is easy to check that all these functions are compatible. Lemma 7.4 allows us to combine them so to obtain novel compatible up-to techniques. For instance the equivalence closure e: $Rel_{\mathcal{D}(S)} \to Rel_{\mathcal{D}(S)}$ can be decomposed as $(id \cup r \cup t \cup s)^\omega$. The fact that e is compatible follows immediately from Lemma 7.4.

In a similar way, we get that that cgr is compatible.

Proof of Proposition 7.3. Observe that cgr $= (id \cup r \cup t \cup s \cup conv)^\omega$. We know that r, s, t and conv (Proposition 7.2) are compatible. Compatibility of cgr follows by Lemma 7.4. $\square$

Since cgr is compatible and thus sound, we can use bisimulation up-to cgr to check $\sim_d$.

Example 7.5. We can now prove that, in the PA depicted in Figure 1, $x_0 \sim_d y_0$. It is easy to see that the relation $R = \{(x_2, y_2), (x_3, y_3), (x_1, \frac{1}{2}y_1 + \frac{1}{2}y_2), (x_0, y_0)\}$ is a bisimulation up-to cgr: consider $(x_1, \frac{1}{2}y_1 + \frac{1}{2}y_2)$ (the other pairs are trivial) and observe that

$$
\begin{array}{ccc}
x_1 \xmapsto{\ a\ } \frac{1}{2}x_1 + \frac{1}{2}x_2 & \qquad & x_1 \xmapsto{\ a\ } \frac{1}{2}x_3 + \frac{1}{2}x_2 \\
\vdots R \qquad\qquad \vdots \mathrm{cgr}(R) & & \vdots R \qquad\qquad \vdots \mathrm{cgr}(R) \\
\frac{1}{2}y_1 + \frac{1}{2}y_2 \xmapsto{\ a\ } \frac{1}{4}y_1 + \frac{3}{4}y_2 & & \frac{1}{2}y_1 + \frac{1}{2}y_2 \xmapsto{\ a\ } \frac{1}{2}y_3 + \frac{1}{2}y_2
\end{array}
$$

---

[7]In [SV16] a similar up-to technique called "up-to lifting" is defined in the context of probabilistic λ-calculus and proven sound.

Since all the transitions of x_1 and $\frac{1}{2}y_1 + \frac{1}{2}y_2$ are obtained as convex combination of the two above, the arriving states are forced to be in $\mathrm{cgr}(R)$. In symbols, if $x_1 \overset{a}{\mapsto} \zeta = p(\frac{1}{2}x_1 + \frac{1}{2}x_2) + \bar{p}(\frac{1}{2}x_3 + \frac{1}{2}x_2)$, then $\frac{1}{2}y_1 + \frac{1}{2}y_2 \overset{a}{\mapsto} \xi = p(\frac{1}{4}y_1 + \frac{3}{4}y_2) + \bar{p}(\frac{1}{2}y_3 + \frac{1}{2}y_2)$ and $(\zeta, \xi) \in \mathrm{cgr}(R)$.

Recall that in Example 7.1, we showed that to prove $x_0 \sim_d y_0$ without up-to techniques one would need an infinite bisimulation. Instead, the relation R in Example 7.5 is a *finite* bisimulation up-to cgr. It turns out that one can always check $\sim_d$ by means of only finite bisimulations up-to. The key to this result is the following theorem, proved in [SW15].

Theorem 7.6. *Congruences of finitely generated convex algebras are finitely generated.* $\quad\square$

This result informs us that for a PA with a finite state space S, $\sim_d \subseteq \mathcal{D}(S) \times \mathcal{D}(S)$ is finitely generated (since $\sim_d$ is a congruence, see Proposition 6.4). In other words there exists a finite relation R such that $\mathrm{cgr}(R) = \sim_d$. Such R is a finite bisimulation up-to cgr:

$$R \subseteq \mathrm{cgr}(R) = \sim_d = \mathrm{b}(\sim_d) = \mathrm{b}(\mathrm{cgr}(R)).$$

Corollary 7.7. *Let $(S, L, \to)$ be a finite PA and let $\zeta_1, \zeta_2 \in \mathcal{D}(S)$ be two distributions such that $\zeta_1 \sim_d \zeta_2$. Then, there exists a finite bisimulation up-to* cgr *R such that $(\zeta_1, \zeta_2) \in R$.* $\quad\square$

This last observation has another pleasant direct consequence: Distribution bisimilarity $\sim_d$ is decidable.

8. Conclusions and Future Work

Belief-state transformers and distribution bisimilarity have a strong coalgebraic foundation which leads to a new proof method – bisimulation up-to convex hull. More interestingly, and somewhat surprisingly, proving distribution bisimilarity can be achieved using only *finite* bisimulation up-to witness. This opens exciting new avenues: Corollary 7.7 gives us hope that bisimulations up-to may play an important role in designing algorithms for automatic equivalence checking of PA, similar to the one played for NDA. Exploring their connections with the algorithms in [HKK14, EHK$^+$13] is our next step.

From a more abstract perspective, our work highlights some limitations of the bialgebraic approach [TP97, Bar04, Kli11]. Despite the fact that our structures are coalgebras on algebras, they are not bialgebras: but still $\approx$ is a congruence and it is amenable to up-to techniques. We believe that *lax* bialgebra may provide some deeper insights.
